

FTPS vs SFTP

PARAMETERS	FTPS	SFTP
		
Connection Security	via SSL/TLS	via SSH channel
Port	990/TCP for the FTPS control channel. 989/TCP for the FTPS data channel.	SFTP port number is 22.
Security	Server authentication is verified using a public key infrastructure. Client authentication can also be performed via username / password or client certificate verification.	Server authentication is achieved by securely distributing the server's public key to clients. Clients can be authenticated using username and password or public key authentication.
Connections Requirement	At least 2 ports required, one port to issue commands and a separate data port for each and every directory listing or file transfer.	Only 1 port is required (commands and data use the same connection).
Algorithms	Asymmetric, symmetric, and key exchange.	Asymmetric, symmetric, and key exchange.
Authentication	Performed via x.509 certificates	Performed via SSH keys
Server Requirements	Requires a server X.509 certificate and private key.	Most SSH server installations will include SFTP support (or Open SSH can be used)
Compatibility	Many functions can sometimes lead to client and server interoperability issues.	SFTP generally is compatible with many modern devices and systems (Linux and Unix) but is not suitable for communicating in legacy like VCL and .NET frameworks.
Configuration	Can cause firewall/transmission issues due to more complex configuration requirement.	Primarily due to its streamlined connections, reduced firewall issues are experienced.
Performance	Offers the highest possible secure transfer speeds.	SFTP is a robust and flexible protocol.
File/Directory Manipulation	FTPS commands are limited and not standardized, hence require additional administrative configuration.	Many standardized controls and commands for activities such as file directory manipulation, permissions locking, etc.
Server to Server Communication	FTPS supports server to server communication.	Server-to-server communications are not well-supported.
